**Background:** Patients with schizophrenia have a higher risk for cardiovascular diseases, which is associated with early mortality compared with the nonschizophrenic population. Early diagnosis of cardiovascular diseases in asymptomatic periods in patients with schizophrenia would enhance their quality of life and reduce mortality. Echocardiography, carotid ultrasonography, and ankle brachial index (ABI) measurement are known to be beneficial methods of detecting subclinical cardiovascular diseases and of risk stratification. The present study investigated carotid intima media thickness (CIMT) and ABI and echocardiographic parameters measured via conventional and tissue Doppler echocardiography in patients with schizophrenia in comparison with a control group.

**Methods:** The present case-control study included 116 patients with schizophrenia and 88 healthy patients. Participants with any current comorbid psychiatric disorder, current or lifetime neurological and medical problems, current coronary artery disease, diabetes, hypertension, hypothyroidism, or hyperthyroidism or who were using antihypertensives, antidiabetic agents, or antiobesity drugs were excluded. High-resolution B-mode ultrasound images were used to measure CIMT. Conventional and tissue Doppler measurements were performed according to the recommendations of the American Society of Echocardiography.

**Results:** Low ABI, mitral ratio of the early (E) to late (A) ventricular filling velocities, septal E', septal S', lateral E', lateral S', septal E'/septal A', lateral E'/lateral A', and high septal A', mitral E'/septal E', mitral E'/lateral E', and CIMT values were observed in the schizophrenia group compared with the control group.

**Conclusion:** Doppler parameters supported the hypothesis that patients with schizophrenia are at high risk for cardiovascular diseases.

**Keywords:** schizophrenia, carotid intima media thickness, ankle brachial index, tissue Doppler echocardiography

## Introduction

Schizophrenia is a chronic, disabling psychiatric disorder with two to three times higher mortality rates than those seen in the general population. The lifetime prevalence is approximately 1% in schizophrenia patients.<sup>1</sup> In addition to the disease's chronicity, patients with schizophrenia have a higher risk for physical diseases, including diabetes, metabolic syndrome, and cardiovascular diseases, compared with the nonschizophrenic population. Quality of life and expected survival are decreased in patients with schizophrenia because of these concomitant chronic diseases.<sup>2-5</sup> Cardiovascular diseases, which are among the leading causes of morbidity and mortality worldwide, are more common in patients with schizophrenia; however, they usually remain underdiagnosed.<sup>6-8</sup> Studies have shown that risk factors for cardiovascular diseases such as obesity,

diabetes, metabolic syndrome, hypertension, dyslipidemia, smoking, and sedentary lifestyle are also more common in patients with schizophrenia than in the nonschizophrenic population.<sup>6,9-13</sup> Treatment of comorbid physical diseases in patients with schizophrenia would enhance quality of life and reduce early deaths. Thus, providing physical health care in addition to mental health care is an important part of the treatment of patients with schizophrenia.<sup>4,14</sup> The following measurements have been recommended for early diagnosis of comorbid physical diseases during the follow-up of patients with schizophrenia: fasting glucose, body mass index (BMI), fasting triglycerides, fasting cholesterol, waist circumference, hip circumference, high-density lipoprotein/low-density lipoprotein ratio (HDL/LDL), blood pressure, and symptoms of diabetes.<sup>15</sup>

Carotid intima media thickness (CIMT) and the ankle brachial index (ABI) are well-studied surrogate markers of early atherosclerosis. It has been demonstrated that CIMT and ABI are in an independent relationship with enhanced vascular morbidity and mortality.<sup>16</sup> ABI is the ratio of the ankle brachial systolic blood pressures; values smaller than 0.90 indicate the presence of atherosclerosis. Low ABI values also serve as a predictor for cardiovascular events and mortality and help identify asymptomatic patients at risk.<sup>17-19</sup> In recent years, CIMT has drawn interest as another predictor of cardiovascular events, and its validity as a suitable measure of atherosclerotic disease has been proven in many studies performed in different populations.<sup>20,21</sup> Doppler echocardiography can accurately assess cardiac output, pulmonary artery pressures, and right- and left-ventricular filling pressures in patients with cardiovascular diseases.<sup>22</sup> In many patients with cardiac disease, diastolic functions are impaired first, followed by systolic functions. Tissue Doppler echocardiography is able to detect diastolic function impairment in its early phase, even in an asymptomatic period.<sup>23,24</sup> Because patients with schizophrenia have a high risk for cardiovascular diseases, monitoring diastolic functions via echocardiography would be beneficial for early diagnosis of cardiovascular diseases. The present study explored ABI, CIMT, and echocardiographic parameters measured via conventional and tissue Doppler echocardiography in patients with schizophrenia without previously known cardiovascular disease in comparison with a healthy control group.

## Materials and methods

### Subjects

The present research is a case-control study. The study group was composed of 116 patients with schizophrenia,

aged between 18 and 65 years (27 women and 89 men), who were recruited from the Mazhar Osman Bakırköy Education and Research Hospital Department of Psychiatry in Istanbul, Turkey. All patients had already met the criteria for schizophrenia according to the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)*.<sup>25</sup> The DSM-IV criteria for schizophrenia were determined using the Turkish version of the Structured Clinical Interview for DSM-IV.<sup>26,27</sup> All patients and healthy control participants were Turkish. Exclusion criteria were any current comorbid psychiatric disorder; current or lifetime neurological and medical problems; current coronary artery disease (CAD); diabetes; hypertension; hypothyroidism; hyperthyroidism; using anti-hypertensives, antidiabetic agents, or antiobesity drugs; and an inability or refusal to provide informed consent.

In addition, 88 healthy control participants (35 women and 53 men) who were age- and BMI-matched were included in the present study. Control patients were selected from among healthy individuals with no clinical evidence of schizophrenia and other psychiatric histories, no current medical problems, no neurologic problems, and no mental retardation. This study was carried out according to the Helsinki Declaration guidelines and was approved by the ethics committee of the Bakırköy Sadi Konuk Education and Research Hospital. Most of the patients were competent enough to provide written informed consent after a full explanation of the procedures of the study. Consent was obtained from the caretakers of patients who were not competent enough to provide written informed consent. All healthy controls accepted to participate in the study, and all of them provided written voluntary informed consent.

### ABI determination

ABI was measured by a single observer in both groups after a 15 minute rest in a supine position. Systolic pressures of brachial arteries of both arms and systolic pressures of both ankles were measured, using a contour-wrapped 12 cm cuff and an 8 MHz Doppler probe (Sonotrax 8-MHz Ultrasonic Vascular Pocket Doppler, Stork Radio, Boca Raton, FL, USA). The cuff was inflated to above the audible systolic pressure (for 20 mm Hg) in each artery. Then, the cuff was slowly deflated and the first audible sound by Doppler probe was recorded as systolic pressure. Six systolic artery pressures (right arm brachial artery, left arm brachial artery, right dorsalis pedis artery, left dorsalis pedis artery, right tibialis posterior artery, left tibialis posterior artery) were measured. Of the same-side dorsalis pedis and tibial posterior artery pressures, the highest one was written on the numerator as the systolic ankle pressure. The highest arm systolic pressure

was written on the denominator, and the ratio of ankle systolic pressure to brachial artery systolic pressure was calculated. The same calculation was performed for the other ankle. The lowest ratio was accepted as the ABI.

### CIMT ultrasound scanning procedure

High-resolution B-mode ultrasound images (GE Vivid I system, GE Healthcare, Milwaukee, WI, USA) (with 3.5 or 5 MHz transducers) with a 7.0 MHz linear array transducer were used to measure CIMT. To measure CIMT, patients were placed in a supine position and asked to turn their heads to the opposite direction of the carotid artery and to keep their necks extended. Measurements were performed at a distance of 1 cm from the bifurcation of the internal and external carotid artery branches. CIMT was measured in the anterior, posterior, and lateral projections. The mean wall thickness of the common carotid artery was used as the key variable for statistical analysis because of its strong association with cardiovascular risk factors. CIMT was considered to be increased when it was more than 0.9 mm, whereas arteriosclerotic plaques were considered to be present when it was 1.5 mm or more.<sup>28</sup> For each variable, the mean value of measurements performed by two readers was used. The interobserver variability was evaluated on the measurements obtained from all patients.

### Echocardiography

Patients were examined in the left lateral decubitus position, using a Vivid I (Vingmed Medical Systems, GE Healthcare, Milwaukee, WI, USA) phased array system equipped with conventional and tissue Doppler technology. Measurements were performed according to the recommendations of the American Society of Echocardiography.<sup>29</sup> The ejection fraction was calculated using Simpson's method.<sup>30</sup> The mitral inflow velocity pattern was recorded using the pulsed-wave Doppler sample volume positioned between the tips of the mitral leaflets. Three consecutive beats were measured and averaged for each parameter. From the apical 4-chamber view, peak early (E) and late (A) transmitral velocities, deceleration time, isovolumetric relaxation and contraction times, and mitral ratio of the E to A ventricular filling velocities were measured. On tissue Doppler imaging, the mitral annular septal and lateral velocities were recorded from the two- and four-chamber views. A 3–5 mm pulse-wave Doppler volume was placed, and tissue Doppler imaging signals were recorded. The Nyquist limit frequency was adjusted to 15–20 cm/second with minimum gain and low-filter settings. Early and late diastolic velocities were obtained.

Systolic myocardial function was evaluated by measuring the peak systolic velocity.

### Statistical analysis

Data were analyzed using Predictive Analytics Soft Ware statistics 18 (IBM Corporation, Armonk, NY, USA). Normality testing was performed by the Kolmogorov–Smirnov test. Descriptive statistics were expressed as frequency tables and cross tables for categorical variables and as a median, minimum, and maximum for numerical variables. Paired comparisons of nonnormally distributed continuous variables were performed using the Mann–Whitney *U*-test. The statistical significance level was set at  $P < 0.05$ .

## Results

### Demographic and clinical properties of participants

One hundred sixteen patients who were diagnosed with schizophrenia and 88 healthy individuals were enrolled in the present study. The median age was 38 years in the patient group (PG) and 38.5 years in the healthy control group (HC). Median age was statistically similar in both groups. The percentage of men (76.72%) was higher in the PG compared with the HC (60.23%;  $P = 0.026$ ). The percentage of women (23.28%) was higher in the PG compared with the HC (39.77%). BMI, rate of smokers, and diagnosis of diabetes mellitus or hypertension were similar between groups. The family history of CAD was more common in the HC. Thirty (25.86%) of 116 patients with schizophrenia had a history of CAD in their first-degree relatives, and 51 (57.96%) of 88 healthy controls reported a family history of CAD in their first-degree relatives ( $P < 0.001$ ). The median values of BMI, serum glucose, serum total cholesterol, serum triglyceride, and serum LDL-cholesterol were found to be similar between groups. Serum HDL-cholesterol level was lower in the PG compared with the HC (36 mg/dL vs 42 mg/dL;  $P < 0.001$ ). The demographic and clinical characteristics of 116 patients with schizophrenia and 88 controls are presented in Table 1.

### Comparisons of ABI, right CIMT, and left CIMT between groups

The median values of ABI were, respectively, 1.07 (0.91–1.38) and 1.16 (0.9–1.45) in the PG and the HC, and ABI was significantly higher in the HC ( $P < 0.001$ ). The median value of right CIMT was 0.58 mm (0.38–1.08 mm) in the PG, which was significantly greater than in the HC (0.51 mm; 0.38–0.69 mm;  $P < 0.001$ ). The median value of left CIMT was 0.56 mm

(0.48–1.17 mm) in the PG, which was also greater than the median value in the HC (0.51 mm; 0.33–0.74;  $P<0.001$ ). ABI and CIMT values of the study groups were presented in Table 2.

## M mode and pulsed-Doppler findings in the PG and HC

The median values of diastolic diameter, systolic diameter, interventricular septum, posterior wall, ejection fraction, mitral E, deceleration time, isovolumetric relaxation time, isovolumetric contraction time, and ejection time were found to be similar between groups. The median A peak value was 74 cm/second (40–124 cm/s) in the PG, which was significantly higher than in the HC (64 cm/s; 33–101 cm/s;  $P=0.003$ ). The median value of diameter of left atrium was longer in the PG compared with the HC (median values of diameters of left atrium of the PG and the HC, respectively: 34 mm [25–45 mm] and 30 mm [23–37 mm];  $P<0.001$ ). The E/A ratio was significantly lower in the PG, at 1.15 (0.58–2.12) compared with in the HC (1.40; 0.76–2.12;

**Table 2** ABI and CIMT in the schizophrenia and control groups

Variable	Schizophrenia group (n=116)	Control group (n=88)	P-value
ABI	1.07 (0.91–1.38)	1.16 (0.9–1.45)	<0.001
Right CIMT (mm)	0.58 (0.38–1.08)	0.51 (0.38–0.69)	<0.001
Left CIMT (mm)	0.56 (0.48–1.17)	0.51 (0.33–0.74)	<0.001

**Note:** Values are presented as median (minimum–maximum).

**Abbreviations:** ABI, ankle brachial index; CIMT, carotid intima media thickness.

$P<0.001$ ). Conventional parameters measured via Doppler echocardiography in the schizophrenia and control groups are presented in Table 3.

## Tissue Doppler parameters in the PG and HC

The mitral annulus septal A' was higher in the PG compared with the HC ( $P<0.001$ ), whereas the mitral annulus septal E', mitral annulus septal S', mitral annulus lateral E', and mitral annulus lateral S' were lower in the PG (respectively,  $P=0.003$ ,  $P<0.001$ ,  $P<0.001$ , and  $P=0.002$ ). The mitral annulus lateral A' was similar between groups. The median values of the mitral annulus septal E'/mitral annulus septal A' ratio and the mitral annulus lateral E'/mitral annulus lateral A' ratio were found to be lower in the PG ( $P<0.001$ ). The median value of the mitral E/mitral annulus septal E' and mitral E/mitral annulus lateral E' ratios were higher in the PG compared with the HC ( $P=0.004$  and  $P<0.001$ , respectively). Tissue Doppler parameters of the study groups are presented in Table 4.

## Discussion

Although no statistically significant difference was found between the schizophrenia and control groups with regard to cardiovascular risk, except for family history of cardiovascular disease, patients with schizophrenia had decreased ABI and increased CIMT, which are markers of subclinical atherosclerosis; no statistically significant difference in

**Table 3** M mode and pulsed-Doppler indices in the schizophrenia and control groups

respect with parameters of two-dimensional and M mode echocardiography; decreased mitral E/A, which is a conventional diastolic parameter; or decreased mitral annulus septal E', mitral annulus lateral E', mitral annulus septal E'/mitral annulus lateral A', and mitral annulus lateral E'/mitral annulus lateral A' or increased tissue Doppler parameters such as mitral E/mitral annulus septal E' and mitral E/mitral annulus lateral E'.

Patients with schizophrenia have a higher risk for cardiovascular diseases and acute myocardial infarction compared with the nonschizophrenic population; therefore, they have an increased risk for mortality resulting from these diseases.<sup>31,32</sup> According to the World Health Organization, eight risk factors (alcohol use, tobacco use, high blood pressure, high BMI, high cholesterol, high blood glucose, low fruit and vegetable intake, and physical inactivity) have accounted for 61% of cardiovascular deaths annually worldwide. The World Health Organization also has reported that less exposure to these risk factors would increase global life expectancy by almost 5 years.<sup>33</sup> It is known that these risk factors are more common in patients with schizophrenia.<sup>34</sup> Early diagnosis of patients with schizophrenia with subclinical atherosclerosis is of great importance in terms of reducing comorbidities and mortality.

In the present study, patients with schizophrenia and control participants were age- and BMI-matched. Participants with any current comorbid psychiatric disorder; current or lifetime neurological or medical problems; current CAD, diabetes, hypertension, hypothyroidism, or hyperthyroidism; or who were using antihypertensives, antidiabetic agents, or antiobesity drugs were excluded.

There were patients who had hypertension and diabetes detected after participation in the study; however, no significant difference was found between the study groups

in terms of the rate of these diseases. Compared with the control group, the schizophrenia group had a higher LDL-cholesterol level with no statistical significance but had a significantly lower HDL-cholesterol level. Total cholesterol and triglyceride levels were similar in the schizophrenia and control groups. It is known that smoking is an important risk factor for cardiovascular diseases. In the study by Kelly et al, the effect of smoking on mortality was investigated in patients with schizophrenia who were aged between 35 and 54 years.<sup>35</sup> The researchers reported that the odds of cardiac-related death were increased 12-fold in smokers compared with nonsmokers. In the present study, the rate of smoking was 55.2%; however, no significant difference was found between the study groups in terms of smoking. Receiving continuous care (ie, 24 hour care), either inpatient care or care in the community, increases the risk for cardiovascular disease in patients with schizophrenia by leading to more smoking and less physical activity.<sup>36</sup> Thus, such a group of patients with schizophrenia should be followed more closely.

ABI is known to be a marker of generalized atherosclerosis<sup>37</sup> and has predictive importance for atherosclerosis.<sup>38</sup> In the present study, the median ABI value was significantly lower in the schizophrenia group than in the control group (1.07 and 1.16, respectively;  $P < 0.001$ ). The statistical power for ABI is calculated as 0.351. These results may show that schizophrenia is an independent risk factor for subclinical atherosclerosis. Considering that low ABI values are the predictors of cardiovascular diseases, closer follow-up may be needed in the schizophrenia group.

The CIMT is also an indicator of subclinical atherosclerosis. Increased CIMT was shown to be a strong indicator of future cardiovascular events.<sup>39</sup> Similarly, that CIMT values were significantly higher in the schizophrenia group than in the control group supported the above-mentioned issue. The statistical power for CIMT was 0.965.

It is a known fact that patients with a family history of CAD are more prone to atherosclerotic diseases.<sup>40</sup> In the present study, the rate of participants with a family history of CAD was significantly higher in the control group compared with that seen in those in the schizophrenia group. In contrast, it is notable that ABI and CIMT have a higher predictive value for cardiovascular diseases in patients with schizophrenia.

Echocardiography and carotid ultrasonography have been reported to be beneficial methods of detecting subclinical cardiovascular diseases and for risk stratification.<sup>41</sup> Tissue Doppler echocardiography, which is similar to routine Doppler ultrasonography, has recently gained importance

in the assessment of blood flow; however, different from Doppler ultrasonography, its technological properties focus on lower-velocity frequency shifts.<sup>42</sup> It has been reported that tissue Doppler echocardiography is beneficial in detecting cardiac dysfunction in the early period.<sup>43,44</sup> The present study found the E/A ratio to be significantly lower in patients with schizophrenia, whereas most tissue Doppler echocardiography parameters were impaired, especially mitral E/mitral annulus septal E' and mitral E/mitral annulus lateral E', which is related to left ventricle end diastolic pressure, compared with those in the control group. The statistical power for E/A was calculated as 0.899. These results, as well, may indicate existing diastolic function and risk for cardiovascular disease; therefore, patients with schizophrenia should be followed-up closely.

The present study has some limitations. First, there might be independent effects of antipsychotic treatment on CIMT and diastolic dysfunction. This is likely the study's major limitation. However, further studies are needed for highlighting the effects of antipsychotic treatment on these parameters. The female/male bias in the patient group also was a limitation of the present study. The sample sizes of groups in the present study might be small for making a general conclusion; that is another limitation of our study.

## Conclusion

The present study found that low ABI and high CIMT values, as well as E/A ratio, and significant differences between the schizophrenia and control groups regarding most of the tissue Doppler parameters, support the hypothesis that patients with schizophrenia have an increased risk for cardiovascular diseases. Moreover, HDL levels were significantly lower in patients with schizophrenia without previously known CAD compared with those in the control group.

To our knowledge, the present study is the first to demonstrate an increased risk for cardiovascular disease in patients with schizophrenia via methods of ABI, CIMT, and tissue Doppler echocardiography. All these findings lead to the conclusion that schizophrenia may be an independent risk factor for atherosclerosis and heart failure. Concomitant physical diseases should be kept in mind during follow-up and treatment of patients with schizophrenia, and the necessary examinations should be performed periodically.

## Neuropsychiatric Disease and Treatment

### Publish your work in this journal

Neuropsychiatric Disease and Treatment is an international, peer-reviewed journal of clinical therapeutics and pharmacology focusing on concise rapid reporting of clinical or pre-clinical studies on a range of neuropsychiatric and neurological disorders. This journal is indexed on PubMed Central, the 'PsycINFO' database and CAS.

Submit your manuscript here: <http://www.dovepress.com/neuropsychiatric-disease-and-treatment-journal>

Dovepress

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
